Descripción del Área Natural Protegida

DESCRIPCIÓN GEOGRÁFICA

El decreto de creación del Parque Nacional Isla Isabel señala *“Que frente a las costas del estado de Nayarit se encuentra ubicada la Isla Isabel, con superficie de 194.17 hectáreas, localizada en las coordenadas 25°52’N y 105°54’W, de la parte más cercana de la tierra, que depende y es administrada por la Federación”*.

Según los resultados obtenidos de los trabajos de georreferenciación efectuados para elaborar el presente programa de conservación y manejo, la superficie total del Parque Nacional Isla Isabel es de 82.1641 hectáreas.

Asimismo, el reciente análisis geográfico de la ubicación de Isla Isabel, revela datos erróneos en las coordenadas señaladas en dicho decreto, siendo su localización precisa la que se detalla en las siguientes coordenadas geográficas extremas:

Latitud Norte	Longitud Oeste
21° 51' 21.84"	105° 53' 31.84"
21° 50' 23.44"	105° 53' 05.56"

Latitud Norte

Longitud Oeste

21° 50' 32.34"

105° 52' 49.64"

21° 50' 56.93"

105° 52' 43.52"

La distancia de Isla Isabel a la costa más cercana, en línea recta a la altura de la ranchería denominada El Colorado y la Laguna de Mexcaltitán es aproximadamente de 28 km al SE; mientras que las Islas Marías se encuentran a 61.5 km al SW de Isla Isabel.

En la costa, los principales poblados que tienen una influencia sobre el parque por la actividad pesquera son San Blas, a 70.3 km y Boca de Camichín a 35 km, ambos pertenecientes al estado de Nayarit y ubicados al SE de la isla, así como Teacapán, en el estado de Sinaloa, a 72 km al NE.

CARACTERÍSTICAS FÍSICAS

Fisiografía

Isla Isabel tiene un origen volcánico, data de aproximadamente 3.5 millones de años (Casas-Andréu, 1992), sus principales elementos geomorfológicos son los restos de aparatos volcánicos, que se manifiestan en las elevaciones, cráteres y acantilados. Las playas son producto en gran proporción de la acumulación de detritos de rocas ígneas, mientras que los acantilados son el resultado de la erosión (marina, eólica y pluvial) y movimientos terrestres verticales ocurridos durante el Pleistoceno Superior (Moore y Curray, 1964 *In*: SAHOP, 1982).

El modelado actual siguió distintos patrones, no obstante, se considera que desde los últimos dos o tres milenios, los climas han sido semejantes a los actuales, por lo que se deduce que las características de las precipitaciones en el periodo de verano influyeron decisivamente en la morfología actual. Ello hace pensar por otra parte, que en la época de sequía los materiales tuvieron contracciones por la acción de la temperatura y el descenso de la humedad, que ocasionó la separación de los materiales que estuvieron a merced de la erosión del viento (Macías, 1979).

Relieve

Elevaciones y acantilados

Isla Isabel presenta un relieve heterogéneo, resultado de sus pendientes, materiales parentales y modelamiento por efecto del agua de lluvia, de escurrimientos
